Submitted 7 March 2007; accepted in final form 15 June 2007

Abstract

Characterization of Na\textsuperscript{+}/H\textsuperscript{+} exchanger NHE8 in cultured renal epithelial cells. Am J Physiol Renal Physiol 293: F761–F766, 2007. First published June 20, 2007; doi:10.1152/ajprenal.00117.2007.—NHE8 is expressed in the apical membrane of the proximal tubule and is predicted to be a Na\textsuperscript{+}/H\textsuperscript{+} exchanger on the basis of its primary amino acid sequence. Functional characterization of native NHE8 in mammalian cells has not been possible to date. We screened a number of polarized renal cell lines for the plasma membrane Na\textsuperscript{+}/H\textsuperscript{+} exchangers on the basis of primary amino acid sequence. Functional characterization of native NHE8 in mammalian cells has not been possible to date. We screened a number of polarized renal cell lines for the plasma membrane Na\textsuperscript{+}/H\textsuperscript{+} exchangers (NHE1, 2, 3, 4, and 8) and found only NHE1 and NHE8 transcripts in NRK cells by RT-PCR. NHE8 protein is expressed in the apical membrane of NRK cells as demonstrated by immunoblots, confocal fluorescent immunocytochemistry, and immunoelectron microscopy. NHE1, on the other hand, is expressed primarily in the basolateral membrane. Bilateral perfusion of NRK cells grown on permeable supports shows Na\textsuperscript{+}/H\textsuperscript{+} exchange activity on both the apical and basolateral membranes. NHE8-specific small interfering RNA knocks down NHE8 protein expression but does not affect NHE1 protein levels. Knockdown of NHE8 protein is accompanied by a commensurate reduction in apical NHE activity, without altered basolateral NHE activity. Conversely, transfection of NHE1-specific small interfering RNA knocks down NHE1 protein expression without affecting NHE8 protein levels and reduces basolateral NHE activity without affecting apical NHE activity. NHE8 is the only apical membrane Na\textsuperscript{+}/H\textsuperscript{+} exchanger in NRK cells. NHE8 activity is Na\textsuperscript{+} dependent, displaying a cooperative sigmoidal relationship, and is highly sensitive to 5-(N-ethyl-n-isopropyl)-amiloride (EIPA). NRK cells provide a useful system where NHE8 can be studied in its native environment.

sodium/proton exchanger; sodium/hydrogen exchanger; proximal tubule

sodium/proton (Na\textsuperscript{+}/H\textsuperscript{+}) exchange is an ubiquitous biological process mediated by integral plasma membrane proteins in cells of all kingdoms. Genes coding for Na\textsuperscript{+}/H\textsuperscript{+} exchangers (NHEs) have been cloned from the simplest prokaryotes (including Archaea) to the most advanced multicellular eukaryotes. The human genome contains nine NHE paralogous isoforms, NHE1–9, with different tissue and subcellular distributions, and one sperm-specific NHE (10, 20). On the bases of their sequence, cellular localization, ion selectivity, and inhibitor specificity, eukaryotic NHEs have been divided into intracellular and plasma membrane subfamilies (10). NHE8 was categorized in a distinct clade (NHE8-like) within the intracellular NHE subfamily (10). NHE8 transcript is ubiquitous, with the highest levels in the kidney, mostly in the proximal tubule (14). When transfected into heterologous systems, NHE8 is an intracellular protein (14, 18). However, in native kidney tissue, NHE8 has also been localized to the apical membrane of the proximal tubule (5, 13).

Na\textsuperscript{+}/H\textsuperscript{+} exchangers are widely distributed in the kidney with segment- and membrane-specific patterns of expression (9). A principal effector of proximal tubule NaCl and NaHCO\textsubscript{3} reabsorption is apical membrane Na\textsuperscript{+}/H\textsuperscript{+} exchange (NHE), which is predominantly mediated by the NHE3 isofrom in adults (2, 6). Mice with genetic deletion of both NHE2 and 3 only have a 50% reduction in proximal tubule Na\textsuperscript{+}-dependent H\textsuperscript{+} secretion compared with wild-type mice, suggesting the presence of another apical NHE isoform in adult proximal tubule (12). The neonatal proximal tubule exhibits significant apical membrane NHE activity despite a paucity of apical NHE3 expression (3, 4, 22). NHE8 has peak expression in cortical brush border membranes in 7- to 14-day-old rats with diminished expression in the adult rat brush border (5), suggesting that NHE8 is the principal neonatal apical membrane NHE isoform. Despite a lower brush border expression, total renal NHE8 protein remains high in adult rats (5), suggesting that NHE8 insertion into the brush border may be a regulatory point.

To date it has not been possible to express mammalian NHE8 at the plasma membrane of cultured cells (13, 18). The only successful attempt in functional characterization of a mammalian NHE8 was by Nakamura and coworkers (18), who expressed recombinant mouse NHE8 in yeast, solubilizing and reconstituting it into artificial proteoliposomes. In this reconstituted system, NHE8 exchanges either Na\textsuperscript{+} or K\textsuperscript{+} for H\textsuperscript{+}, which is more reflective of an intracellular than an apical membrane NHE. A similar approach was employed by Kang et al. and coworkers (15) to characterize the transport kinetics of an insect homolog (AeNHE8) from the mosquito Aedes aegypti. The present study aimed to identify a mammalian NHE8 in cultured renal epithelial cells. Am J Physiol Renal Physiol 293: F761–F766, 2007.

EXPERIMENTAL PROCEDURES

Materials and supplies. All chemicals were obtained from Sigma (St. Louis, MO), except where otherwise noted, and except for the following: culture media, Lipofectamine 2000, TRIzol reagent, Thermoscript RT-PCR system and BCECF-AM (Invitrogen, Carlsbad, CA). The costs of publication of this article were defrayed in part by the payment of page charges. The article must therefore be hereby marked “advertisement” in accordance with 18 U.S.C. Section 1734 solely to indicate this fact.
CA); penicillin and streptomycin (Cambrex, East Rutherford, NJ); 
EZ-Link sulfo-NHS-SS-biotin and immunopure immobilized streptavidin (Pierce, Rockford, IL); horseradish peroxidase-labeled anti-
mouse IgG and blotting-grade nonfat dry milk (Bio-Rad Laboratories, 
Hercules, CA); enhanced chemiluminescence detection kit (Amer-
sham Biosciences, Piscataway, NJ); polyvinylidene difluoride mem-
branes (Immobilon, Millipore, Billerica, MA).

**Cell culture.** NRK cells (normal rat kidney polarized epithelial cells, 
American Type Culture Collection, Manassas, VA) cultured at 
37°C in a 95% air-5% CO2 atmosphere were passaged in high-glucose 
(450 mg/dl) DMEM supplemented with 10% fetal bovine serum, 
penicillin (100 U/ml), and streptomycin (100 g/ml). Before study, 
confluent cells were rendered quiescent by incubation in serum-free 
DMEM.

**RT-PCR.** Total cellular RNA was extracted by using TRIzol re-
agent, and cDNA was obtained by oligo(dt) primed reverse transcrip-
tion using the ThermoScript system (50°C, 40 min). PCR was per-
formed for 30 cycles with denaturation at 94°C (30 s), annealing at 
53°C (40 s), and extension at 72°C (4 min). The following rat NHE 
isoform-specific primers were used for PCR: NHE1 forward 5’-AGTCGTGGATCCTGGTAA-3’; NHE1 reverse 5’-CAC-
TAGCCCTGGCTACTGC-3’; NHE2 forward 5’-CAGCCGCACAT-
TGCTCTACAA-3’; NHE2 reverse 5’-TGTCGGAGTCTGCTGAT-
ATTA-3’; NHE3 forward 5’-AATTCCTGAGATCGGATCTG-3’; NHE3 reverse 5’-CTCTGGTCACAGACTGCTA-3’; NHE4 forward 5’-
GGCTGGGATTGAAGATGTATGT-3’; NHE4 reverse 5’-ATTA-3’;
NHE8 forward 5’-GGCTGGGATTGAAGATGTATGT-3’; NHE8 reverse 5’-
AAGGGTTTACAGATCTTG-3’.

**Antibodies and immunoblotting.** The following primary antibodies 
were used: anti-NHE8 monoclonal antibody 7A11 (13), anti-NHE1 
multiclonal antibody 4E9 and chicken anti-rat NHE1 polyclonal 
antibody (Chemicon/Millipore, Billerica, MA), rabbit anti-rat NHE3 
polyclonal antibody no. 1314 (2), and anti-β-actin monoclonal anti-
body (Sigma). Immunoblotting was performed as described previ-
ously (8). Briefly, NRK cells were homogenized in RIPA buffer (150 
mM NaCl, 50 mM Tris-HCl, pH 7.4, 5 mM EDTA, 1% Triton X-100, 
0.5% deoxycholate, and 0.1% SDS) containing fresh protease inhib-
itors and cleared by centrifugation (14,000 g, 4°C, 30 min), and 
protein content was determined by the method of Bradford. Identi-
cal amounts of protein were heated for 2 min at 95°C in loading buffer, 
size fractionated by SDS-PAGE, and electrophoretically transferred to 
polyvinylidene difluoride membranes. Membranes were blocked in 
nonfat milk, probed overnight at 4°C with the appropriate primary 
antibody, washed (0.05% Tween 20 in PBS), incubated with a horseradish peroxidase-labeled secondary antibody for 1 h, washed as 
above, and visualized by enhanced chemiluminescence. For repro-
bing, membranes were first stripped (30 min at 50°C in 0.125 M 
Tris·HCl, pH 6.7, with 4% SDS and 0.016% β-mercaptoethanol) 
and then reprobed as above. Protein abundances were quantified by 
densitometry using the Scion/NIH Image software (Scion, Freder-
ick, MD).

**Apical membrane protein expression.** Confluent quiescent cells 
were rinsed with ice-cold isotonic wash buffer as above and surface 
proteins were biotinylated by incubating cells with 1.5 mg/ml sulfo-
NHS-SS-biotin in 10 mM triethanolamine (pH 7.4); 2 mM CaCl2, and 
150 mM NaCl for 90 min with horizontal motion at 4°C. After 
labeling, plates were washed twice with 6 ml of quenching buffer 
(PBS containing 1 mM MgCl2, 0.1 mM CaCl2, and 100 mM glycerine) 
for 20 min at 4°C. Cells were then lysed in RIPA buffer with protease 
inhibitors as above, lysates were cleared by centrifugation, and the 
supernatants were diluted to 2.5 mg/ml of protein with RIPA buffer. 
Cell lysates of equivalent amount of protein were equilibrated over-
night with streptavidin-agarose beads at 4°C. Beads were washed 
sequentially with solutions A (50 mM Tris·HCl, pH 7.4, 100 mM 
NaCl, 5 mM EDTA), B (50 mM Tris·HCl, pH 7.4, 500 mM NaCl), and 
C (50 mM Tris·HCl, pH 7.4). Biotinylated proteins were released 
by heating to 95°C in loading buffer and subjected to immunoblotting 
as above.

**Immunocytochemistry.** NRK cells were fixed in 4% paraformalde-
hyde in PBS for 10 min, permeabilized in 0.1% Triton X-100 in PBS 
for 3 min, and blocked by 1.5% BSA and 10% goat serum in PBS 
for 1 h. Specimens were incubated with anti-NHE8 monoclonal antibody 
(1:50 dilution) overnight at 4°C, followed by incubation with FITC-
conjugated goat anti-mouse antibody (1:800 dilution, Invitrogen) 
for 1 h and rhodamine-conjugated phalloidin (1:50 dilution, Invitrogen) 
for 20 min. Images were visualized with a Zeiss LSM-510 confocal 
microscope.

**Immunoelectron microscopy.** NRK cells grown on permeable filters 
(0.4-μm pore size, Corning) were fixed in 4% paraformaldehyde at 
4°C for 20 min. The immunogold labeling of ultrathin frozen sections 
was performed according to the method of Tokuyasu (23). The cells 
were infiltrated with 2.3 M sucrose overnight and frozen in liquid 
nitrogen, and 80-nm sections were cut on a Leica ultracytometric 
microscope (Leica Ultracut UCT) and mounted on Formvar-coated nickel 
girds. The sections were processed with the following steps: rehydration 
with PBS containing 20 mM glycine for 10 min followed by PBS 
containing 1.5% BSA in PBS for 15 min; incubation with anti-
NHE8 monoclonal antibody (1:10) for 60 min; washing with 1.5% 
BSA in PBS and then PBS; incubation with colloidal gold-conjugated 
anti-mouse IgG antibody (10-nm gold particles, diluted 1:5, Sigma) 
for 60 min; washing with PBS; washing in water; and staining with 
a mixture (8:5:1) of 3% methylcellulose-water-3% uranyl acetate. 
Samples were visualized with a JEOL 1200 EX transmission electron 
microscope.

**NHE activity assays.** NHE activity was measured fluorometrically 
by using the intracellularly trapped pH-sensitive dye BCECF as 
described previously (11). Cells grown on either glass coverslips or 
permeable supports were loaded with 10 μM BCECF-AM (25 min at 
37°C), and intracellular pH (pHi) was estimated from the ratio of 
fluorescence (excitation wavelengths: 500 and 450 nm, emission 
wavelength: 530 nm) in a computer-controlled spectrofluorometer 
(QM-8/2003, Photon Technology International, London, Ontario, 
Canada). The 500/450 nm fluorescence ratio was calibrated to pH, 
using K’migerin as described (1). Bilateral (apical and basolateral) 
perfusions were performed to separately measure Na+/H+ exchange 
activity on apical and basolateral membranes. For these experiments, 
NRK cells were grown to confluence on permeable supports (0.4-μm 
 pore size, Corning, Corning, NY), and epithelial integrity was 
asessed by both transepithelial electrical resistance and [3H]inulin 
permeability. Cells were loaded with BCECF and mounted in a 
cuvette chamber where both the apical and basolateral sides can be 
perfused independently and simultaneously. Na’-containing solution 
was applied to one side while the opposite side was continuously 
perfused with a Na’-free solution containing 1 mM of the NHE 
inhibitor 5-(N-ethyl-N-isopropyl)-amiloride (EIPA). For H’+ kinetic 
experiments, confluent NRK cells were loaded with BCECF and 
adifferent to pH values by incubation with the K’/H’+ ionophore nigericin at different extracellular K’ concentrations. For 
all experiments Na’/H’ exchange activity was assayed as the initial 
rate of the Na’-dependent pH, increase after an acid load in the 
absence of CO2/HCO3-, and results are reported as d pH/dt, where t is 
time. Comparisons were always made between cells of the same 
passage studied on the same day. For K’/H’ exchange activity 
experiments, confluent NRK cells were loaded with BCECF and 
adified by the NHCl prepulse method (17), and K’+ was added to 
the apical membrane in the absence of external Na+. Exogenously 
administered nigericin provided a positive control for detection of 
K’/H’ exchange activity.

**RNA interference.** Small interfering RNA (siRNA) duplexes were 
designed by using the web-based BLOCK-iT RNAi Designer soft-
ware from Invitrogen. Knockdown was achieved by cotransfection of 
two specific nonoverlapping Stealth RNAi duplexes (Invitrogen) 
per gene. For transfection of siRNA, NRK cells were grown to ~50%
Characterization of NHE8 in Cultured Renal Cells

Identification of NHE8 transcript in NRK cells. RT-PCR using isoform-specific primers for all renal plasma membrane Na\(^{+}/H^{+}\) exchangers (7) identified two plasma membrane NHE transcripts in NRK cells, NHE8 and NHE1 (Fig. 1). All PCR products were confirmed by direct sequencing.

Localization of NHE8 protein in NRK cells. Both NHE8 and NHE1 proteins were detected in total NRK cell lysate by immunoblotting, but only NHE8 was accessible to surface biotinylation of confluent monolayers grown on plastic (Fig. 2A), showing that NHE8 is expressed on the apical membrane. Consistent with the absence of NHE3 mRNA, NHE3 protein was not detected in NRK cells by use of several polyclonal and monoclonal antibodies (not shown). Fluorescence immunocytochemistry (Fig. 2B) and immunogold labeling electron microscopy (Fig. 2C) confirmed the localization of NHE8 at the apical membrane of NRK cells.

Functional characterization of apical NHE8. To determine whether NHE8 on the apical membrane of NRK cells is a functional Na\(^{+}/H^{+}\) exchanger, while excluding the potential confounding effects of basolateral NHE1, we measured NHE activity on the apical side of the NRK monolayer while perfusing the basolateral side with a Na\(^{+}\)-free isotonic solution containing 1 mM EIPA as described in EXPERIMENTAL PROCEDURES. The high concentration of EIPA and the lack of extracellular sodium, maintained constant by continuous perfusion, exclude the possibility of basolateral Na\(^{+}/H^{+}\) exchange in these conditions. Figure 3A shows a typical tracing of Na\(^{+}\)-dependent cell pH recovery in these conditions. Apical NHE activity is pH\(_{i}\) dependent (Fig. 3B), sodium dependent displaying a cooperative sigmoidal relationship (Fig. 3C), and highly sensitive to EIPA (Fig. 3D). To determine whether native apical NHE8 also exchanges K\(^{+}\) for H\(^{+}\), we looked for potassium-dependent pH\(_{i}\) recovery after an acid load as described in EXPERIMENTAL PROCEDURES. There was no detectable apical K\(^{+}/H^{+}\) exchange in NRK cells (Fig. 3E).

Knockdown of NHE8 in NRK cells. To confirm that apical NHE activity in NRK cells is mediated by NHE8, we knocked down NHE8 expression by RNA interference. NHE8 protein expression was lowest 72 h after siRNA transfection, whereas NHE1 expression was not changed (Fig. 4A). Apical NHE activity was significantly reduced 72 h after siRNA transfection, commensurate with the reduction in NHE8 protein, whereas basolateral NHE activity was not changed (Fig. 4B). These findings constitute a further validation of the apical localization and function of NHE8 in NRK cells.

Knockdown of NHE1 in NRK cells. To exclude the potential contribution of NHE1 to apical NHE activity, we knocked down NHE1 expression by RNA interference. After 72 h NHE1 protein expression was significantly reduced, whereas NHE8 expression was not changed (Fig. 5A). Consistent with the presence of NHE1 only on the basolateral membrane, apical membrane NHE activity was not changed, whereas basolateral NHE activity was significantly reduced (Fig. 5B).
DISCUSSION

We have shown for the first time that native apical membrane NHE8 is a functional Na\(^+\)/H\(^+\) exchanger in a mammalian cell membrane. NRK cells are polarized cells natively expressing apical membrane NHE8 and basolateral membrane NHE1 and not expressing other plasma membrane NHE isoforms. We have demonstrated that apical Na\(^+\)/H\(^+\) exchange activity in NRK cells is mediated by NHE8.

NHE8 transcript and protein are expressed in the proximal tubule from S1 through S3, and NHE8 protein is detected in brush border membrane vesicles by immunoblot and in the proximal tubule apical membrane by immunohistochemistry using both polyclonal antisera and monoclonal antibodies (5, 13). Correspondingly, there is evidence that NHE3 is not the sole mediator of proximal tubule apical Na\(^+\)/H\(^+\) exchange. NHE3\(^{-/-}\) mice have only a 50% reduction in brush border Na\(^+\)/H\(^+\) secretion compared with NHE3\(^{+/+}\) mice, and neonatal rat proximal tubules have significant luminal

Fig. 3. Apical NHE8 activity and functional characterization. A: typical tracing of Na\(^+\)-dependent cell pH recovery. Confluent NRK cells on permeable supports were loaded with the pH-sensitive fluorescent dye BCECF and mounted in a cuvette chamber where both the apical and basolateral sides can be perfused independently and simultaneously. Cells were acidified by the nigericin method and cell pH was monitored by epifluorescence. Na\(^+\) addition was made to the apical chamber while the basolateral chamber had a Na\(^+\)-free continuous perfusate containing 1 mM EIPA. B: proton kinetics. NRK cells were acidified to different intracellular pH (pHi) values by use of nigericin at different extracellular K\(^+\) concentrations, and apical Na\(^+\)-dependent pH recovery was measured with constant external Na\(^+\) (brackets denote concentration). The data shown is a summary of 3 independent experiments performed on different NRK cells. C: sodium kinetics. Apical Na\(^+\)-dependent pH recovery after acidification to the same pHi by nigericin was measured with different external Na\(^+\) concentrations. The data shown is a summary of 3 independent experiments performed on different NRK cells. D: ethyl-isopropylamiloride (EIPA) kinetics. Apical Na\(^+\)-dependent pH recovery after acidification to the same pHi by nigericin was measured with varying amounts of EIPA and constant Na\(^+\). The data shown is a summary of 3 independent experiments performed on different NRK cells. E: typical tracings of the K\(^+\)/H\(^+\) exchange assay. Apical K\(^+\)-dependent pH recovery after acidification by the NH\(_4\)Cl prepulse method was examined in the absence of external Na\(^+\). Exogenously administered nigericin served as positive control.

Fig. 4. Knockdown of NHE8 in NRK cells. A: NRK cells were transfected with 2 sets of NHE8-specific small interfering RNA (siRNA) duplexes, and whole cell lysates were resolved on SDS-PAGE and immunoblotted for NHE8 and NHE1 (monoclonal antibody), 72 h after transfection. B: NHE activity was assayed as Na\(^+\)-dependent pH recovery after an acid load by use of BCECF fluorescence under V\(_{\text{max}}\) conditions for both Na\(^+\) and H\(^+\) either on the apical or basolateral surface, 72 h after transfection with either control or NHE8-specific siRNA.

Fig. 5. Knockdown of NHE1 in NRK cells. A: NRK cells were transfected with 2 sets of NHE1-specific siRNA duplexes and whole cell lysates were resolved on SDS-PAGE and immunoblotted for NHE8 and NHE1 (polyclonal antibody), 72 h after transfection. B: NHE activity was assayed as Na\(^+\)-dependent pH recovery after an acid load using BCECF fluorescence under V\(_{\text{max}}\) conditions for both Na\(^+\) and H\(^+\) on either the apical or the basolateral surface, 72 h after transfection with either control or NHE1-specific siRNA.
Na⁺-dependent H⁺ secretion despite almost no apical NHE3 expression. In both cases, the non-NHE3-mediated Na⁺/H⁺ exchange activity has been shown to be sensitive to EIPA (12, 22). An insect homolog of mammalian NHE8 has recently been shown to be EIPA sensitive when heterologously expressed in NHE-null rodent fibroblasts (15). Congruently, our study has determined that the activity of native mammalian NHE8 at the apical membrane of NRK cells is highly EIPA sensitive. Taken together, these findings provide strong evidence that proximal tubule apical NHE8 is a functional transporter in vivo.

Congruent with the findings of Nakamura and coworkers (18), NHE8 may also have an intracellular distribution and function. The presence of NHE8 antigen in the poststreptavidin fraction (Fig. 2A) is compatible with this hypothesis. However, one must exercise caution because the presence of NHE8 in the poststreptavidin lysate does not definitively resolve the issue of intracellular NHE8. First, biotinylation may be incomplete owing to hidden lysine residues, and even surface NHE8 may appear in the supernatant. Second, nonbiotinylated NHE8 may just be a reflection of the protein during its normal cycle of intracellular synthesis and trafficking to and from the plasma membrane, which is universal for any membrane protein.

It is noteworthy that the previously reported EIPA sensitivity of the residual NHE activity in NHE3−/− mice (12) is at variance with another published study, which found no component of EIPA-sensitive transtubular bicarbonate absorption in NHE3 null mice (24). However, this apparent contradiction could easily be explained by differences in the execution of the respective processes, which are discussed in detail in reference (12). Experimental conditions activating or inhibiting proximal tubular NHE8 could further explain the molecular basis of this discrepancy.

The sigmoidal relationship between extracellular Na⁺ concentration and NHE8 activity in our experiments suggests cooperativity in sodium binding. This finding is different from the Michaelis-Menten sodium kinetics of other NHEs studied in heterologous expression systems (16, 19). However, kinetic evidence, suggesting cooperativity of sodium/proton exchange in renal brush border membrane vesicles, has been previously reported, and it has been suggested that cooperativity may result from the association of NHE8 in cooperative dimers (21). Our findings may reflect the association of NHE8 proteins in functionally cooperative dimers at the plasma membrane of NRK cells, but further studies are required to investigate this hypothesis.

Of note, it is not appropriate to compare relative expression and activity of apical NHE8 and basolateral NHE1 in cultured cells. These quantitative parameters depend on cell culture conditions (including growth on coverslips and serum deprivation) and would not reflect the relative expression and activity of NHE8 and NHE1 in renal cells in vivo.

Prior to the present study, the function of NHE8 had been examined by using NHE8 protein expressed and purified from yeast and reconstituted in proteoliposomes (15, 18). This system is limited by absence of the native plasma membrane milieu, cytoskeleton, and protein interaction network. Moreover, reconstitution in proteoliposomes may actually be a model better reflecting the intracellular function of NHE8, since both Na⁺/H⁺ and K⁺/H⁺ exchange activity have been described in this system (15, 18). There may be significant differences between the function and regulation of the ubiquitously expressed intracellular NHE8 and the renal proximal tubule apical membrane NHE8. The absence of detectable apical K⁺/H⁺ exchange in NRK cells could be a reflection of these differences.

This body of data shows that native NHE8 is targeted to the plasma membrane in a mammalian renal cell line and functions as an apical Na⁺/H⁺ exchanger. Proximal tubule brush border NHE8 and NHE3 are reciprocally regulated during early postnatal development (5), but the factors involved in these developmental changes and in the regulation of NHE8 require further investigation. NRK cells will furnish a valuable system for further studies on the function and regulation of NHE8.
